

STEPS4 - One-Page App Summary

Source basis: README.md, Swift source, extension targets, and repo audits.

WHAT IT IS

Steps4 is an iOS SwiftUI app that converts daily activity into spendable experience.

Users spend that experience to open time-limited access to selected apps or app groups.

WHO IT IS FOR

Primary persona: iPhone users who want structured self-control for distracting apps, using an earn-then-unlock model tied to health and daily actions.

WHAT IT DOES (KEY FEATURES)

- Converts HealthKit steps and sleep into daily energy/experience.
- Tracks body/mind/heart daily selections within a 100-point model.
- Uses PayGate sessions to spend balance for unlock intervals.
- Supports ticket groups, per-app/group settings, and minute charging.
- Applies Family Controls + ManagedSettings shields via DeviceActivity.
- Syncs stats, selections, settings, and snapshots to Supabase.

VISUAL STYLE AND METAPHORS (REPO EVIDENCE)

- Data-driven gradient maps steps/sleep to warm/cool/dark opacity.
- Theme metaphor in code comments: daylight = paper-like resistance; night = screen context.
- Visual language emphasizes high-contrast text, thin strokes, yellow marker accent (#FFD369), and expressive headline fonts.

HOW IT WORKS (ARCHITECTURE - REPO EVIDENCE)

- Components: SwiftUI views + AppModel + stores (HealthStore, BlockingStore, UserEconomyStore).
- Services: HealthKitService, FamilyControlsService, NotificationManager, SupabaseSyncService actor, AuthenticationService, persistence/cloud services.
- Extensions: DeviceActivityMonitor, ShieldConfiguration, ShieldAction.
- Data flow: HealthKit + selections -> AppModel recalculates balance -> PayGate/minute events spend -> shields update -> local persistence + Supabase sync.

HOW TO RUN (MINIMAL)

1. Open /Users/kpudan/dev/xcode/Steps4/Steps4.xcodeproj (scheme: Steps4).
2. Set SUPABASE_URL and SUPABASE_ANON_KEY for app target.
3. Build/run (simulator): `xcodebuild -project Steps4.xcodeproj -scheme Steps4 \ -destination 'platform=iOS Simulator,name=iPhone 16' -configuration Debug build`
4. Physical device is recommended for FamilyControls/DeviceActivity behavior.
5. Exact backend provisioning/seed steps: Not found in repo.
